Taxonomic Revision of *Sagitta robusta* and *Sagitta ferox* Doncaster, and Notes on Their Distribution in the Pacific

ANGELES ALVARÍNÖ

The material for this study was provided by the monthly cruises of the California Cooperative Fisheries Investigation (CalCOFI) during 1954 and 1958, and by the following expeditions of Scripps Institution of Oceanography in the Pacific Ocean: Northern Holiday (1951), Shellback (1952), Capricorn (1952–53), Transpac (1953), East Tropic (1955), North Pacific (1955), POFO (1955), Troll (1955), Chinook (1956), Equapac Horizon (1956), Equapac Stranger (1956), Downwind (1957), Tethys (1960), and a few samples from the Naga (1959–61).

Thirty species of Chaetognatha were found in the plankton samples from the Pacific expeditions; 24 of these were observed also in the 2,000 samples examined from the area covered by the CalCOFI cruises off California in 1954 and 1958. The identities of two of the species found, *Sagitta robusta* Doncaster and *S. ferox* Doncaster, are confused in the literature. The principal aim of this article is to discuss and establish the valid taxonomic characteristics of these two species prior to publishing a study of the distribution and abundance of the chaetognaths in the area of the CalCOFI cruises.

**TAXONOMIC NOTES**

A clear statement on the systematics of these species was perhaps difficult, in the past, since only a small number of specimens was available. The various Scripps expeditions cover an extensive distributional area in the Pacific. The numerous plankton samples collected are generally well preserved, providing good material for an accurate taxonomic study. A large number of *S. robusta* and *S. ferox* specimens, therefore, have been carefully examined.

*S. robusta* Doncaster and *S. ferox* Doncaster could be included in a taxonomic group with their closest relatives *S. hispida* Conant, *S. helena* Ritter-Zahony of the Atlantic, and *S. bipunctata* Quoy and Gaimard, a cosmopolitan species. They have strong, firm bodies, because of the well-developed muscles, small lateral fields, large heads, and conspicuous collarettes.

*S. robusta* and *S. ferox*, although very closely related, can be easily distinguished by several characteristics which appear consistently in each. These two species are found in equatorial and tropical Pacific waters, spreading to the subtropical region. They both have a firm, opaque body, strong muscles, large head, and a well-developed collarette. One of the species is smaller than the other. The smaller has the characteristics of *S. robusta* Doncaster and the larger those of *S. ferox* Doncaster. However, the size notations recorded in this study do not agree with the size Doncaster (1903) reports in the original description. This fact shows that perhaps for some reason the size notations in the original descriptions are erroneous. Similar discrepancies are found in successive revisions.

The taxonomic confusion in the literature is explained by the fact that Doncaster (1903) originally applied one series of characteristics to the smaller species and the other series to the larger. His first description of *S. robusta* and *S. ferox* is incomplete; nevertheless a few well-defined characteristics given by Doncaster provide good reason for separating the two species.

The main distinctive characteristics for both *S. robusta* (a) and *S. ferox* (b) in the original description (Doncaster 1903) are as follows:

(a) "posterior fins reach the seminal vesicles;"

(b) "do not quite reach the seminal vesicles;"

(a) "ovaries extremely long and extend in fully mature specimens to the anterior transverse septum;"

1 Scripps Institution of Oceanography, University of California, San Diego, California. Manuscript received June 1, 1961.
Sagitta robusta Doncaster and S. ferox—Alvariño

(b) "long as in S. robusta, but do not quite reach the front end of the trunk cavity";
(a) "seminal vesicles touch both posterior and tail fins, project somewhat,"
(b) "project slightly";
(a) "hooks 7–8, usually 8;"
(b) "hooks 5–6."

Doncaster also gives S. robusta a very important characteristic; namely "the anterior fin’s front end is opposite the posterior end of the abdominal ganglion." This distinctive characteristic is the clue for a clear-cut separation of the two species.

Size is the one difference between Doncaster’s diagnosis and those studied here. He gives a mature size of 16 mm for S. robusta and of 12 mm for S. ferox, whereas the specimens from the Pacific and China Sea collections with the characteristics of S. ferox mature when at least 16 mm in length, and specimens with the characteristics of S. robusta when at sizes 8–12 mm.

This size discrepancy could be a misprint in the original description, and has apparently been the cause of the controversy regarding the identity of these species and the resultant mistaken identifications which have been published. Apparently many authors separate these species by size alone, disregarding the other anatomical features. For this reason, specimens with the characteristics of S. ferox have been considered as S. robusta and vice versa. The belief that the sizes were inadvertently transposed from one species to the other in the original description is supported by the fact that the specimens from the Pacific Expeditions consistently have the characteristics of S. robusta with sizes 8–12 mm and S. ferox with a size of 16 mm.

Descriptions of S. robusta and S. ferox found in material from the Pacific and China Sea collections follow.

Sagitta robusta Doncaster

Total length when mature, 8–12 mm.
Average % tail length in relation to the total length, 27.5.
Head large, but smaller than in S. ferox (Fig. 1).
The clove-shaped body is strong, firm, broad, of nearly uniform width from the neck to the tail septum. It is opaque because of the strong longitudinal muscles (Fig. 2d). Lateral fields small.

Collarette well developed, extends from the head to the posterior end of the ventral ganglion, spreading to the tail as a thin layer that becomes thicker in front of the anterior end of the seminal vesicles.

The corona ciliata was not studied because it could not be seen clearly in preserved material; therefore it was of small value for identification purposes.

Gut diverticula present and rather conspicuous.

The anterior fins are shorter than the posterior fins. They extend up to the level of the posterior end of the ventral ganglion. They are wider than in S. ferox and no rayless zone is present.

The posterior fins are rounded. They lie more on the tail than on the trunk. About 2/3 of the length of the fin lies on the tail segment. The posterior fins are wider at a point slightly behind or in front of the tail septum. A small rayless zone appears at the internal portion of the fins, in front of the tail septum, by the external openings of the female organs.

The distance between both the anterior fins and the posterior fins is longer than in S. ferox.

The seminal vesicles (Fig. 3) are conspicuous even in the young species. They touch both tail fin and posterior end of the posterior fins. They

Fig. 1. Head of S. robusta Doncaster.
have a well-developed head and a voluminous posterior sperm sac, and rupture occurs ventrally at the anterior lateral side. The seminal vesicles in *S. robusta* resemble in shape those of *S. bipunctata*. In both *S. robusta* and *S. bipunctata* there is swelling of the collarette tissue on the tail in front of the anterior end of the seminal vesicles, but in *S. bipunctata* the posterior fins do not touch the seminal vesicles as in *S. robusta*, and the distance between the anterior end of the seminal vesicles and the posterior end of the posterior fins is occupied by the particular swelling of the collarette tissue.

The ovaries are long, reaching from the neck
Sagitta robusta and S. ferox—Alvarino

**FIG. 3. S. robusta, seminal vesicles, ventral view.**

...to the anterior septum in the fully mature specimens. The ova are round and arranged in one row in the ovaries (Fig. 4).

Hooks 7–8. This notation is unusually constant.

Anterior teeth 6–9.
Posterior teeth 10–15.

The eye pigment is concentrated as in Figure 5. The shape of the pigmented area is similar in both *S. robusta* and *S. ferox* but in *S. ferox* the longitudinal axis of the ellipse is longer in relation to the transverse axis.

*S. robusta* from the CalCOFI and from part of the Shellback samples mature when 7–8 mm in length. The mature specimens are smaller at the eastern edge of the distributional area, that is, off the southern part of Baja California and the southern part of Mexico. This fact is probably due in many cases to an increase in temperature.

**Sagitta ferox** Doncaster

Total length when mature, 16–18 mm without tail fin.

Average % of tail segment in relation to total length, 26.5.

The body is rigid, firm, with the same width from the neck to the tail septum. The longitudinal and transverse muscles are strong. The lateral fields are narrow. In general resembles a clove, as does *S. robusta*, but larger in size and with well-defined characteristics which permit easy differentiation of the species (Fig. 6d).

The head is large (Fig. 7).

The eyes are as shown in Figure 8.

The collarette is well developed, extending from the head to the anterior end of the anterior fins.

**FIG. 4. S. robusta, lateral view of left ovary. Detail of the disposition of the ova.**
Anterior fins reach the level of the middle of the ventral ganglion. They are longer than the posterior fins. No rayless zone is present. They are narrower and longer in comparison to the total size than in *S. robusta*.

The posterior fins are rounded and triangular in shape. They are wider at a point behind the tail septum. They extend approximately the same distance on the trunk as on the tail, or slightly more on the tail. They present an interior rayless zone which extends from the level of the tail septum to the final anterior end of the fins.

Both anterior and posterior fins are rather close laterally.

The seminal vesicles almost touch both the posterior fins and the tail fin, but are not as conspicuous in the early stages as in *S. robusta*. However, they are very noticeable when full or at the last stage of maturity of the male organs. The rupture occurs by a lateral opening (Fig. 9a,b).

The ovaries reach the neck region completely filling the body cavity when fully mature. The ova when ripe, are wider than long and are dorso-ventrally arranged in two or three rows. (Fig. 10.)

Gut diverticula present.

Hooks 5-6, usually 6, and this notation appears particularly constant.
Anterior teeth 7-10, usually 9.
Posterior teeth 12-14.
Specimens of *S. robusta* from the Naga Expedition are fully mature when 12 mm in length. Specimens from the Equapac Horizon and Stranger are mature when 10 mm, and from the CalCOFI and Shellback area when 7-8 mm. In the measurements the tail fin was not included.

Doncaster (1903) gives a few well-defined characteristics for *S. robusta* and *S. ferox*, but an incomplete description (Table 1).
Fowler (1906) redescribes both in more detail and also gives their respective distribution areas and temperature ranges on pages 42, 45, 55, 69, 72, 76, 77, and 78. He states for *S. ferox*:
"it gets mature at 15 mm., while S. robusta at about 12 mm. Anterior fins commencing about on a level with the abdominal ganglion. Posterior fins shorter than anterior fins, more on the tail than on the trunk, extending to the seminal vesicles, widest behind the septum. Tail fin generally rounded." And for S. ferox: "head fairly large, but smaller than in S. robusta. Body proportionally more slender than in S. ferox. Anterior fins long, beginning at or just behind the abdominal ganglion. Posterior fins larger than anterior fins (unlike S. ferox) more on the tail than on the trunk, widest behind the septum, reaching to the seminal vesiculae when they are bursting." (See Table 2.)

Kofoid (1907) keeps both S. robusta and S. ferox as valid species.

Michael (1908) identifies both S. robusta and S. ferox and characterizes S. robusta with posterior fins as long or longer than the anterior fins, and S. ferox with posterior fins shorter than the anterior fins. The same author in 1911 and 1913

places S. robusta under the S. hispida synonymy and keeps S. ferox.

Ritter-Zahony (1909a, b; 1910; 1911a, b) places S. ferox under the S. robusta synonymy.

Baldasseroni (1915) reports S. robusta and states: "in some specimens the anterior fins reached the posterior end of the ventral ganglion while in others the anterior fins extended to the middle of the ventral ganglion." Accordingly, he recognizes both S. robusta and S. ferox.

Michael (1919) redescribes both species and gives taxonomic validity to both (Table 3).

Burfield and Harvey (1926) compare the identities of both species with others and S. ferox is included under the S. robusta synonymy. Burfield and Harvey’s drawings no. 33, 34, 35, 37, and perhaps no. 36 do not correspond to S. robusta, but agree with S. ferox.

In the present article only those publications which give diagnostic details as well as drawings to enforce the identification were considered.

Tokioka (1939) describes Sagitta ai as a new species and states at the end of the description:

FIG. 8. S. ferox, left eye.
It is possible that *S. ferox* Doncaster reported by Fowler (1906) from the SIBOGA area is identical with the present species, though there are some differences in the shape of the seminal vesicle, collarette and in some other minute characteristics. However, *S. ferox*, described originally by Doncaster, seems to be not quite identical with the same species reported by Fowler, since there is no characteristic in common to both forms, except for the number of hooks. ... the present form is fished from the surface waters mingled with *S. robusta* with no intermediate form being found, the former is much fewer than the latter.

*Sagitta ai* Tokioka has morphological characteristics identical to *S. ferox* Doncaster, according to the original description, redescription (Fowler, 1906), and redescription (Michael, 1919).
The description of *Sagitta ai* Tokioka (1939) agrees with *S. ferox* Doncaster but not as to size. It is also identical to that of *S. ferox* Fowler (1906) and Michael (1919), even to the number of hooks. This meristic characteristic is not very helpful for identification purposes as the number of hooks and teeth vary with the changes in the environment, but, strangely enough, in the case of *S. robusta* and *S. ferox* it remains more constant. Perhaps the factors affecting these numerical changes remain at a constant level in the area they occupy.

Because of the general aspect of the body, length of the ovaries, seminal vesicles, and the important characteristic of longer anterior fins than posterior fins, Delman’s (1939) drawing of *S. planctonis* is *S. ferox* and not *S. robusta* as Thomson (1947) states, due to the fact that *S. robusta* has shorter anterior than posterior fins. Tokioka’s (1940a: 372) description and drawings of *S. robusta* Doncaster and *Sagitta ai* Tokioka, correspond with the redescription for both *S. robusta* and *S. ferox* as well as with the identifications obtained in the present study.

The disposition and proportion of the fins, more than that of the seminal vesicles, suggest that *Sagitta ai* Tokioka (1942) is more likely to be *S. robusta* than *S. ferox* Doncaster. After comparing the seminal vesicles shown in Tokioka’s figure 9 (1942: 540) with those of specimen plate VII, figure 3, the conclusion could be drawn that different specimens are involved.

</table>
Thomson (1947: 14) says: "but in Doncaster’s original description S. robusta was given as reaching 16 mm. and S. ferox only about 13 mm." He, too, is aware of some error in the original description by Doncaster.

Burfield (1950) records only S. robusta although S. ferox could also be found in that area.

Tokioka (1952) in the list of Chaetognatha includes under the synonymy of S. ferox "(S. hispida of some authors, S. japonica Galzow, S. robusta of many authors)," but Sagitta ai is placed under the S. robusta synonymy. However, the same author (1940b) speaks of both S. robusta Doncaster and Sagitta ai Tokioka.

Tokioka (1955) states: "front end of the anterior fins reaches the middle of the ganglion in S. robusta." This statement does not agree with Tokioka (1940a: 372, fig. 5, A) or with Doncaster (1903), Fowler (1906), or Michael (1919).

It is likely that specimens of 22 mm in length are S. planctonis or S. zetesios, rather than S. robusta or S. ferox as Thomson (1947) reports.

According to the drawings given by Rao and Ganapati (1958) their S. robusta is probably S. ferox.

In the Shellback stations where Tokioka (1959) reports S. ferox f. americana, specimens with the characteristics of S. robusta are recorded in this study. It is obvious that Tokioka’s description of S. ferox f. americana agrees with the definition here obtained of S. robusta as well as with Tokioka’s description of S. robusta (1940a), but is somewhat smaller. Tokioka (1959) gives for his S. ferox f. americana a medium size of 8.3 mm long and states that "fully swollen seminal vesicles are found in 6.2 mm. long individuals" (Table 4).

In the present study it was found that S. robusta appears with the seminal vesicles well developed when the individuals are still small, and that the species is very protandrous. The seminal vesicles are conspicuous from an early stage to the most advanced stage in the animal’s life, unlike those of S. ferox, and much like S. serratodentata Krohn, S. pseudoserratodentata Tokioka, and S. pacifica Tokioka.

The specimens recorded from the Shellback Expedition, where Tokioka reports S. ferox f. americana, have characteristics that agree completely with the previous descriptions of S. robusta.

In order to follow as accurately as possible the taxonomic descriptions by the original authors as well as the redescriptions, it was decided that this revision should name S. robusta and S. ferox the species with the characteristics iden-

Tables 1-5, with the respective differential in characteristics for the species from Doncaster, Fowler, Michael and Tokioka's *S. ai* and *S. ferox americana*, give complementary and comparative information.

**Distribution**

*S. robusta* is equatorial in distribution, extending more to the east than *S. ferox*. It spreads north in the eastern part of the tropical region, invading the waters off Mexico, from the southern part of Baja California southward. The distribution of *S. robusta* (Fig. 11) is more patchy and not as continuous as *S. ferox*. *S. robusta* was observed mainly in the deeper tows, whereas *S. ferox* appears more often in the upper layers. A difference in the distribution in depth might be the reason for this uneven distribution.

*S. ferox* occurs along the equatorial and tropical regions of the Pacific, extending northwards into the central waters (Fig. 12).

The distribution of *S. robusta* and *S. ferox* reported by Bieri (1959) corresponds respectively to *S. ferox* and *S. robusta*.
