Dear Mr. Houghtailing:

Subject: Newtown Site "D"
Preliminary Soil Report
(for site grading for townhouse
development)
Waimalu, Ewa, Oahu, Hawaii
Tax Map Key: 9-8-02: Por. 9

Transmitted herewith is our preliminary soil exploration report for site grading design considerations for the proposed townhouse development site for Newtown Site "D" at Waimalu, Ewa, Oahu, Hawaii.

This report includes a Boring Location Sketch, boring logs, laboratory test results, recommendations and limitations.

Respectfully submitted,

WALTER LUM ASSOCIATES, INC.

NEWTOWN SITE "D"
PRELIMINARY SOIL REPORT

WAIMALU, EWA, OAHU, HAWAII
TAX MAP KEY: 9-8-02: POR. 9

SCOPE OF EXPLORATION

The purpose of this exploration was to evaluate general soil conditions for site grading design for townhouse development for the proposed Newtown Site "D" at Waimalu, Ewa, Oahu, Hawaii.

This report includes field explorations, laboratory tests, general site grading design recommendations and limitations.

This report does not include swimming pool work and conditions resulting from pool construction.

FIELD EXPLORATION

Twenty-six exploratory borings were made at the site. The locations of these borings are shown on the Boring Location Sketch. Descriptions of the underlying soils encountered are shown on the boring logs.

Also attached are logs of borings previously made for "Newtown Estates 2nd Access Road - Phase I"; "Newtown Estates 2nd Access Road - Phase II"; and "Newtown Estates Recreation Center, Park and School Site."

Borings were made with 3 and 4-in. diameter augers using carbide drag and finger type bits. Soil samples were recovered with 2-in. thin-wall tube samplers and a standard split spoon sampler driven with a 140-lb hammer falling 30 inches.

LABORATORY TESTS

Laboratory tests included: natural water content, unconfined compression, laboratory vane shear, Atterberg limit, grain-size analysis, specific gravity, AASHO T-180-73I density and CBR.

A summary of the laboratory test results is given in Tables IA thru IE

SOIL CLASSIFICATION SYSTEM

Soil samples were visually observed and subjected to appropriate tests in the laboratory. Based on visual observations and laboratory tests, the soil descriptions given on the boring logs are generally made in accordance with the "Unified Soil Classification System."

SOIL DESCRIPTION BY OTHERS

From a review of the U. S. Soil Conservation Service maps of the area, the surface soils described by others are as follows:

U. S. Soil Conservation Service, "Soil Survey of Islands of Kauai, Oahu, Maui, Molokai and Lanai, State of Hawaii," August 1972:

LaB, Lahaina silty clay (CL-ML soils)

3 to 7 percent slopes

LaC, Lahaina silty clay (CL-ML soils)

7 to 15 percent slopes.

GENERAL SITE CONDITIONS

The proposed site is located on a ridge about 1/4 mile north of the H-1 Freeway and between Waimalu Stream and Punanani Stream in Waimalu, Ewa, Oahu, Hawaii.

The site is an abandoned sugarcane field. Lined and unlined ditches and access roads cross the site.

The existing ground generally slopes down toward the southwest at about 10 to 25% grades. Steeper slopes to about 50% were noted along the east and west boundaries of the site.

INTERPRETATION OF SOIL CONDITIONS

From the field exploration and laboratory test results, the soils may be generally approximated as follows:

Stiff to hard reddish-brown clayey silts and silty clays (MH soils) to about 15 to 30 ft, the depths drilled.

Decomposed rock or boulders were encountered in several borings.

Pockets of clay "CH" soils were encountered in several borings.

Water was not noted in the borings during the field explorations.

Variations to the above soil conditions are to be expected in localized areas. For more detailed descriptions of soils encountered in the borings, refer to the boring logs.

DISCUSSION AND RECOMMENDATIONS

In general, the proposed plan is to clear and grade the site for a townhouse development.

Cuts from little to about 30 ft are planned generally in the upper areas and fills from little to about 10 ft in height are planned generally in the lower areas.

The preliminary site plans indicate that some of the buildings may be situated on cut and/or fill slopes. Because surface soils on slopes tend to creep, building on slopes should generally be avoided, otherwise, they should be designed on an individual basis for each building.

The plans also indicate that some of the buildings will be located along the existing cane haul road near the south boundary. Because miscellaneous fill may have been placed in localized sections along the roadway or shoulder areas, hard and soft pockets and boulders may be encountered. Field adjustments may be made as such conditions occur.

Two retaining walls about 60 to 90 ft in length and about 1 to 4 ft in height are proposed along the roadway near the east boundary. The walls will be located on slopes with about 2 to 3 horizontal to 1 vertical ratios.

If practicable, walls on slopes should generally be avoided. If they are unavoidable, substantial, well-drained, flexible type walls should be considered. Maintenance and future adjustments should be allowed for.

Because of decomposed rocks encountered in some borings, boulders may be anticipated in the excavations. Boulders may be used to construct fill slopes or open areas outside of probable building sites.

If boulder fill areas are not available or are filled up during construction, other provisions should be made for the disposal of excess boulders.

Site Grading

In general, the on-site soils may be used for the construction of the proposed fills. Grading work should be done as required by the Revised Ordinances of Honolulu, 1969 As Amended and as recommended below:

1. The area should be cleared and grubbed.

Surface vegetation and miscellaneous debris

should be cleared and removed prior to site filling.

2. Topsoil and stockpiled soils should be stripped to stiff natural ground before placement of fills. Loose surface soils at finish grades should be scarified and recompacted.
3. Localized soft pockets encountered during site preparation should be excavated and replaced with select material compacted in thin lifts.
4. Hard surfaces of existing haul roads should be scarified down to stiff soils and recompacted to match the density of the surrounding soil.
5. Where fills are proposed on sidehill areas, gullies and in drainage and irrigation ditches, loose material at the bottom and sides should be stripped down to stiff natural

ground. Rock blankets with subdrains and/or buttress fills should be considered before the placement of fills.

6. Thin sidehill fills (sliver fills) on sloping areas should be avoided.
7. Trenches should be cut in a herringbone pattern along the bottom and sides of natural drainage-ways or dips before the placement of fills. Subdrains should be placed in the trenches. The locations of subdrains should be determined in the field after clearing and grubbing.
8. Fills should be constructed in approximately level layers starting at the lower end and working upward. Where fills are made on sloping areas steeper than about 5 horizontal to 1 vertical, the ground at the toe of the fill should be benched to a generally level condition. As the fill is brought up, it should continually be keyed into the stiff natural ground by cutting steps into the slopes and compacting the fill into these steps.

9. If boulders are proposed to be used in the construction of fills, they should be generally placed along the toe sections of fill slopes and outside of probable building sites. Before placing the boulders, the subgrade should be stripped to stiff natural ground and shaped to drain. A transition layer of select granular material (6 in. to dust sizes) should be placed on the subgrade and the boulders placed on the select material. A transition layer of select granular material should also be placed against the boulders before earth fills are placed against the boulders. Earth fill may be used in the void spaces between boulders. See attached sketch, Figure 1.

10. Fills should be laid in 6-in. compacted layers to 90% of the maximum density determined by the AASHO T-180-73I test method. In roadway areas, the top 2 ft of fill should be compacted to 95% of the maximum density.
11. Provisions should be included to drain the site during and after filling operations.

Slopes

In general, cut and fill slopes of 2 horizontal to 1 vertical or flatter should be used.

If slope heights (top to toe) of greater than 15 ft are considered, 8-ft-wide benches should be placed at height intervals of about 15 ft.

To minimize erosion, the runoff from rainstorms should be diverted away from slopes by berms or ditches whenever practicable.

The surface of fill slopes should be compacted by cat-tracking or with a sheepfoot roller.

Slope planting is recommended on cut and fill slopes to minimize erosion.

Slope adjustments or other precautions may be necessary if seepage zones, expansive clay pockets or soft spots are encountered in localized areas. In general, when clay pockets are encountered in slopes, they should be removed and replaced with select material compacted in thin lifts.

Foundations

In general, light, 2-story wood-frame townhouse structures are proposed.

The preliminary grading plan indicates that some units would be located on fairly level ground and others on sloping ground or near the tops of slopes.

In general, buildings should be avoided on sloping hillsides where the slopes are steeper than 3 horizontal to 1 vertical ratio. For building sites steeper than 3 to 1, the building site foundations should be evaluated on an individual site basis.

Low, basement type retaining walls are planned for the 2-story wood-frame structures. Some movements should be anticipated. Structural members, where practicable, should be designed with connections or joints that would allow for some movements. Substantial well-drained walls should be considered.

If foundations are located over or adjacent to a utility trench, the foundations should be designed to span over the trench and the footings should extend below the bottom of the trench.

Buildings on fairly level ground

On fairly level sites, where the proposed buildings are located 15 ft away from the top of slopes, conventional foundations such as slab-on-ground and post-and-beam construction may be used.

Where clay "CH" soils occur near finish grade, the area below the building and to about 5 ft beyond the perimeter of the building should be graded such that there is about 3 ft of selected non-expansive soils below finish grade and bottoms of footings.

Buildings on sloping ground

On sloping sites and near the tops of slopes, post-and-beam type foundation construction is recommended.

Where the lot grades are steeper than about 5 to 1 or where the building is located within 15 ft from the top of a slope or retaining wall, deep foundations are recommended.

Where the lot grades are flatter than 5 to 1, deep foot blocks may be considered (see Figure 2).

Deep foundations for light, 2-story wood-frame townhouse structures may be designed with small diameter pipe piles. The piles should generally extend below an imaginary plane drawn upward from the toe of slope at about a 4 horizontal to 1 vertical slope with a minimum pile length of about 6 ft. A maximum pile length of about 20 ft may be considered for most situations. The foot blocks should be tied in the up and down direction of the slope to counteract the downhill creep effects of the surface soils (see Figure 2). For 2-1/2 in. or 3 in. diameter pipe piles, allowable loads of about 6 kips per pile may be used.

In general, the light townhouse structures should be designed to accommodate and resist some creep of the ground surface. Odd-shaped and split level structures should be minimized or designed to tolerate surface creep of the ground. The use of masonry walls should be discouraged or used with care and designed to tolerate surface creep of the ground.

General foundation guidelines for light residential structures

1. Because of the downhill creep effect of soils on a slope, some settlements may occur near

the tops of slopes. Buildings and retaining walls should generally be placed about 15 ft or more from the tops of slopes.

2. Next to or along the tops of slopes, structures should be designed as small units or floating platforms or decks resting on posts and beams that will allow the floors to be leveled should settlements occur. Odd-shaped and split level structures should be minimized or designed to float as a unit.

3. Bearing values for a given soil usually vary with the size and depth of footings. For the proposed light, wood-frame structures, bearing values of about 2000 p.s.f. may be used for footings on stiff natural ground or on compacted fill.

Loads of about 6,000 pounds per pipe pile or per deep footing may be considered.

4. If foundations are located over or near a utility trench, they should be designed to span over the trench and the bottoms of footings should extend below the bottom of the trench.

5. Soft spots, clay "CH" soils and pockets of loose material encountered in footing

excavations or below the building area should be excavated and replaced with selected on-site soils, fairly well-graded granular material such as S4C or other approved material compacted in thin lifts.

6. The bottom of footing excavations should be recompacted before pouring of concrete.
7. Construction of retaining walls on slopes should generally be avoided or designed with care.
8. Good surface drainage away from the structures should be maintained and the site should be graded to prevent the ponding of water.

Residential Retaining Walls

According to the preliminary plans, retaining walls are planned within the residential structures. The walls will retain the soils beneath the garages and support parts of the structures.

The use of masonry walls should be discouraged or used with care. The walls should be designed to tolerate surface creep of the ground.

The excavation for walls should be made preferably after the site has been graded and compacted. Where walls occur, the slopes should be overfilled, compacted and then excavated for retaining walls.

In general, the bottom of walls should rest on stiff natural ground or on compacted select material. Soft or loose pockets at the bottom of wall footing excavations should be removed and replaced with well-graded granular material or low grade concrete.

On compacted fills on sloping ground, deep foundations are recommended (see Figure 2).

Fairly well-graded granular material or select granular material should be used for backfilling behind the walls. Backfill behind masonry walls should not be compacted by water tamping.

To minimize the effects of ground moisture, subdrains behind and below the bottom of walls and waterproofing of the walls are recommended.

Bearing values of about 3000 p.s.f. may be used for wall foundations resting on stiff natural ground or on compacted

select fill. The bearing values may be somewhat increased for the toe pressures.

For lateral earth pressures, assuming select well-drained backfill, the following equivalent fluid pressure may be used:

60 p.c.f. for retaining walls restrained at top.

In addition, lateral earth pressures should be added for anticipated vehicular loads. The center of pressure should be considered to act somewhat above the lower third of the triangular fluid pressure diagram, assuming that subdrainage and drainage of the backfill are provided.

For sliding resistance between the base and subgrade, a coefficient of friction of 0.40 may be used provided the base of the wall is well drained, and there is sufficient (2 times the base) stiff natural ground or compacted select material in front of the toe of the wall (see Figure 2).

Roadway Retaining Walls

Two retaining walls about 60 and 90 ft in length with heights varying from about 1 to 4 ft are proposed along the roadway at the east boundary of the site.

The existing ground slopes down at about 2 to 3 horizontal to 1 vertical slopes and is covered with haole koa, brush and boulders. Boring No. 11 indicated about 4 ft of soil over decomposed rock.

The walls will retain fills about 2 to 6 ft high and sloping upward from the top of the walls at 2 horizontal to 1 vertical slopes.

In general, surface soils along a slope tend to creep. To minimize creep effects, the wall foundations should extend below the creep zone of the surface soils. The foundations should extend down to rocky material or 2 footing widths horizontally away from the slope face (see Figure 3).

Fairly well-graded material or select granular material should be used for backfilling behind the walls.

Bearing values of about 3000 p.s.f. may be used for wall foundations resting on stiff natural ground or on rocky material. The bearing values may be somewhat increased for the toe pressures.

For lateral earth pressures, assuming select well-drained backfill, the following equivalent fluid pressure may be used:

45 p.c.f. for retaining walls unrestrained at top.

In addition, lateral earth pressures should be added for anticipated vehicular loads. For a sloping backfill, the lateral pressure should be increased according to the Rankine theory, or the earth pressure charts by Terzaghi & Peck, or other similar accepted theory. The center of pressure should be considered to act somewhat above the lower third of the triangular fluid pressure diagram, assuming that subdrainage and drainage of the backfill are provided.

For sliding resistance between the base and subgrade, a coefficient of friction of 0.40 may be used provided the base of the wall is well drained, and there is sufficient (2 times the base) stiff natural ground or rocky material in front of the toe of the wall (see Figure 3).

Subdrains should be placed behind the walls below the foundation level and daylighted to drain.

Slab on Ground

Capillary moisture

To minimize the capillary rise of water from underlying soils, concrete slabs on ground should be placed over a base course of 4 in. of well-graded gravel less than

3/4-in. and greater than 1/4-in. in size or some form of capillary break. If practicable, the subgrade generally should be kept slightly higher than the finish grade outside the building and shaped to drain.

Expansive soils

The soils may be slightly expansive. To minimize the expansive effects, the subgrade below slabs on ground should be scarified and recompacted on the wet side of optimum and pre-wetted several days prior to pouring of concrete.

To minimize the heave or wavy surface effects at the ground floor level, non-bearing partitions, doors, cabinets, etc., should be designed with loose fits and other precautions taken to allow for some future adjustments or maintenance.

Roadway and Parking Area

In general, for light automobile traffic and drained subgrade conditions, an estimate of the roadway pavement thickness may be as follows:

1. Wearing course - 2-in. asphaltic concrete.
2. Base course - 6-in. base course.
3. Subbase - 6-in. select borrow over
a prepared subgrade.

Provisions should be made in the contract documents to allow for local adjustments regarding select borrow subbase and borrow material requirements in the field in accordance with the design standards of the City and County of Honolulu. In fill areas, the use of select soils within the top 2 to 3 ft of the subgrade may reduce the thickness of or eliminate the need for the select borrow subbase or borrow courses.

The subgrade should be compacted and shaped to drain. To avoid the ponding of water and softening of the subgrade at low points, weep holes thru the walls of the catch basins or subdrains that daylight should be placed at subgrade levels in these low areas.

Underground Utilities

Underground utilities should be placed after the fills are constructed.

The bottom of utility trenches should be daylighted and graded to shed water, particularly near the tops and toes of slopes. The backfill and drainage of these utility trenches should be carefully designed.

Flexible connections should be used.

Unforeseen Conditions

Because of the variability of soil deposits, site improvements, designs and construction techniques, conditions may be encountered that cannot be foreseen with even the most exhaustive studies of site and project conditions. These unforeseen conditions should be recognized and then evaluated so that the designs or the construction methods may be modified accordingly, if necessary.

Unforeseen or undetected conditions such as soft spots, existing utility trenches, structure foundations, voids or cavities, old tunnels, boulders, expansive soil pockets or seepage water, etc., may occur in localized areas and will have to be adjusted and corrected in the field as they are detected.

Site Regrading

After mass grading work is done and cuts and fills are made according to the grading plans, regrading at some future date should be avoided unless done under the guidance of a soils engineer.

PROPOSED SPECIFICATION FOR EARTHWORK

NEWTOWN SITE "D"

General Description

This item shall consist of clearing and grubbing, preparing of land to be filled, excavating and filling of the land, spreading, compacting and testing of the fill, and subsidiary work for grading the site.

Clearing, Grubbing and Preparing Areas to be Filled

Vegetation, rubbish and miscellaneous material shall be removed and disposed of, leaving the disturbed area with a neat, debris-free appearance.

Topsoil and stockpiled soils shall be stripped to stiff natural ground before the placement of fills. Loose surface soils encountered at finish grade shall be scarified and recompacted.

Hard surfaces of existing haul roads shall be scarified down to stiff soils and recompacted to match the density of the surrounding soil.

The bottom and sides of gullies or natural drainageways shall be stripped down to stiff natural ground before the placement of fills.

Trenches shall be cut in a herringbone pattern and subdrains placed in the trenches to provide drainage paths for the bottom and sides of natural drainageways or dips before the placement of fills.

Where fills are made on sloping areas steeper than 5 horizontal to 1 vertical, the ground at the toe of the slope shall be benched to a generally level condition. As the fill is brought up, it shall continually be keyed into the stiff natural ground by cutting steps into the slopes and compacting the fill into these steps.

Materials

Fill material shall consist of selected on-site soils or approved borrow soils. The soils shall contain no more than a trace of organic and deleterious matter.

Borrow soils shall be select soils generally less than 6-in. maximum size, with more than 30% fines and a plasticity index generally less than 20.

Fill material placed in the top 2 ft of fills shall contain less than 30% gravel.

Placing, Spreading and Compacting Fill Material

The selected fill material shall be placed in level layers which, when compacted, shall not exceed 6 inches. Each layer shall be spread evenly and blade-mixed during the spreading to attain uniformity of material and water content within each layer.

Rocks or cobbles shall not be allowed to nest and voids between rocks shall be filled and compacted with small stones or earth.

When the water content of the fill material is well below the optimum for compacting purposes, water shall be added until the water content is near the optimum.

When the water content of the material is well above the optimum for compacting purposes, the fill material shall be aerated by blading or by other satisfactory methods until the water content is near the optimum.

After each layer has been placed, mixed and spread evenly, it shall be compacted to 90% of maximum density in accordance with AASHO Test No. T-180-73I or other comparable density tests. For fills in roadway areas, the top 2 ft of fill shall be compacted to 95% of the maximum density. Compaction shall be with sheepsfoot rollers, multiple-wheel pneumatic-tired rollers or other acceptable rollers which shall be able to compact the fill to the specified density. Rolling shall be accomplished while the fill material is at the specified water content. The rolling of each layer shall be continuous over the area and the roller shall make sufficient passes to obtain the desired density.

Field density tests shall be made to get an indication of the compaction of the fill. Where sheepsfoot rollers are used, the soil may be disturbed to a depth of several inches. Density readings shall be taken as often as necessary in the compacted material below the disturbed surface. When these readings indicate that the density of a layer of fill or portion thereof is below the required density, that layer or portion shall be reworked until the required density has been obtained.

The fill operation shall be continued in 6-in. compacted layers, as specified above, until the fill has been brought to the finished slopes and grades as shown on the accepted plans.

Boulder Fills

If boulders are used for the construction of fills, they shall be generally placed along the toe section of slopes and outside of probable building sites. The subgrade shall be stripped to stiff natural ground,

shaped to drain and a transition layer of select granular material (6 in. to dust sizes) shall be placed on it. The boulders shall be placed on the select granular material. A transition layer of select granular material shall be placed against the boulders before construction of earth fills against the boulders. Earth fill may be used in the void spaces between boulders.

Excavation

Suitable material from excavation shall be used in the fill and unsuitable material from excavation shall be disposed of.

Unforeseen Conditions

If unforeseen or undetected soil conditions such as soft spots, existing utility trenches, structure foundations, voids or cavities, boulders, seepage water or expansive soil pockets, etc., are encountered, corrective measures shall be made in the field as they are detected.

Rainy Weather

Fill material shall not be placed, spread or rolled during unfavorable weather conditions. When the work is interrupted by heavy rain, fill operations shall not be resumed until field tests indicate that the water content and density are as previously specified.

BORING LOGS

The stratification lines shown on each of the boring logs represent the approximate boundary between soil types and the transition may be gradual.

Symbols

Symbols used generally are in accordance with the Unified Soil Classification System.

Where a parenthesis "(MH)" is used, the soil sample was classified by visual observation of the sample recovered.

Where no parenthesis "MH" is used, the soil sample was classified from either the Atterberg limit or sieve analysis test results.

LIMITATIONS

In general, soil formations are commonly erratic and rarely uniform or regular. The boring logs indicate the approximate subsurface soil conditions encountered only at the drill holes where the borings were made at the times designated on the logs and may not represent conditions at other locations or at other dates. Soil conditions and water levels may change with the passage of time and construction methods or improvements at the site.

During construction, should subsurface conditions much different from those in the borings be observed, encountered, or otherwise indicated, we should be advised immediately to review or reconsider our recommendations in light of the new developments.

If there is a substantial lapse of time between the submission of this report and the start of work at the site, or if conditions have changed due to natural causes, plan changes, or construction operations at or adjacent to the site, it is recommended that this report be reviewed to determine the applicability of the recommendations considering the time lapse, changed conditions, and changes in the state of the art of soil engineering.

Our professional services were performed, findings obtained and recommendations prepared in accordance with generally accepted engineering practices. This warranty is in lieu of all other warranties expressed or implied.
