

Nutritive Values of Some Hawaii Foods

IN HOUSEHOLD UNITS AND COMMON MEASURES

Carey D. Miller

Barbara Branhoover

HAWAII AGRICULTURAL EXPERIMENT STATION
Circular 52

June 1957

THE AUTHORS

Carey D. Miller is Nutritionist at the Station, Head of the Department of Foods and Nutrition of the College of Agriculture, and Professor of Foods and Nutrition, University of Hawaii.

Barbara Branthover was Junior Nutritionist at the Station, 1950-55.

ACKNOWLEDGMENT

Mildred Ige, Laboratory Attendant at the Station Foods and Nutrition Department, gave valuable assistance in weighing foods, and in calculating and checking the nutritive values for the various portions.

Third printing, June 1966

Fourth printing, September 1969

Fifth printing, December 1973

PREFACE

Government publications such as Agricultural Handbook 8 (22), and its revisions, and private publications such as Bowes and Church (1) give the nutritive values of many common American foods in household units and/or average servings. This circular presents nutritive values for some foods available in Hawaii which are not found in the above publications and it is expected to be used as a supplement to the larger and more complete compilations.

More values for Oriental foods used in Hawaii were originally planned but shortage of staff made it impossible to carry out the analyses in time to include the results in this edition.

Selection and preparation of samples: Measurements were made on fresh products of top quality purchased on the market. Waste sections were removed prior to measurements so that all weights are for the edible portion (E.P.) unless otherwise indicated. A.P. means as purchased.

Weighing and measuring of samples: Vegetables such as spinach, cowpea tender tips, and watercress were first cut into 1-inch sections before weighing and measuring. Raw cup weights of vegetables were obtained from tossing the vegetable sections into the cup and tapping it lightly once or twice. Cup measures are averages of at least triplicate weighings.

Cooking of vegetables: Vegetables were cooked by the common household procedure of boiling gently in a small amount of water until tender. If the water was not all absorbed, the vegetable was drained in a sieve for 3 minutes before weighing and measuring, though it is recommended that to retain maximum nutritive values, the water in which most vegetables are cooked should be served with the vegetable. (Our vitamin assays of cooked vegetables were made on steamed products which retained all juices.)

Cooking of rice: The usual American methods of cooking rice employ more water than the typical Oriental method used in Hawaii, which is as follows: Cold water is added to the washed rice in a saucepan or kettle with a tight-fitting cover; the water is brought to the boiling point and boiled for about 5 minutes, then the heat is reduced and the contents of the pot allowed to steam for varying periods of time from 20 to 40 minutes. This method results in a drier product which has a different proportion of nutrients than rice boiled in a large amount of water or rice cooked in a double boiler. The values given for rice in this circular are based largely on figures obtained in our laboratory plus a few published figures.

Sources of original data: Most of the figures have been derived from published and unpublished analyses of foods made in the Station laboratories, but in the case of some foods or for one or more nutrients the values have been taken from other sources listed under *References*. No effort has been made to indicate the exact source for each figure since the average user is not interested in such details.

When some of the values were obtained from sources other than our own analyses, they were calculated to the same moisture content as our products. If all our values were not determined on the same sample, they were calculated to the same moisture basis.

Calculation of caloric values: Instead of using the older energy factors of 4, 9, and 4 for protein, fat, and carbohydrate, all energy values (calories) have been recalculated, using the more specific physiological energy factors for different types of foods recommended by the Human Nutrition Research Branch of the Agricultural Research Service, U. S. D. A. (4). For soybean products, the factors given in a later publication were used (4a).

Calculations of nutritive value of cooked foods: The figures for many of the cooked foods have been derived from the raw on the basis of change of weight in the cooked product, especially for proximate composition and the three minerals. However, for the vitamin values of cooked foods most of the figures are based on our analyses, especially from Technical Bulletin 30 (16). Since we have not determined the mineral losses of cooked vegetables, or other foods (except for losses in washing rice), we have assumed that there are no losses in minerals for the cooked product, but this would be true only if vegetables were carefully prepared and cooked to retain all the liquid and, therefore, all of the minerals that might be soluble.

0 indicates that no detectable amount of the nutrient was present in the sample tested.

Trace indicates that in the samples tested there were detectable amounts of the vitamin, but for 100 grams the values were *less than* 10 I. U. for vitamin A, 10 micrograms for thiamine and riboflavin, 0.10 milligram for niacin, and 1.0 milligram for ascorbic acid.

Blanks indicate that no data are available, and the nutrient may or may not be present.

Figures in parentheses () are derived from a similar product, are imputed values, or for some reason are considered doubtful.

The following abbreviations have been used in the table headings in order to conserve space:

Prot.—protein

CHO—carbohydrate

Ca—calcium

P—phosphorus

Fe—iron

I. U.—International Units (for vitamin A)

Gm.—grams (28.4 grams equal 1 ounce)

Mg.—milligrams (1000 mg. equal 1 gram)

Mcg.—micrograms (1000 mcg. equal 1 mg.)
